### **2.B.1. Introduction**

In Utah's 2006 Integrated Report, Great Salt Lake (GSL) is not included in any assessment category. Public comment on the Integrated Report raised concerns related to the condition of the GSL and cited evidence of potential nutrient enrichment in Farmington Bay, elevated water-column mercury concentrations, and findings of mercury accumulation in the avian species frequenting GSL. In response to the public comments received on the Integrated Report (IR), the Utah Division of Water Quality (UDWQ) and the Environmental Protection Agency (EPA) formed a collaborative workgroup. The purpose of the workgroup was to develop a process to assess the ability of GSL to support its beneficial uses as designated under the Clean Water Act. Because of the unique characteristics of GSL and the lack of assigned numeric criteria, the State's Assessment Methodology does not currently address GSL. The decision making approach described in this appendix serves as a guide to development of an assessment methodology for the GSL.

This appendix describes the proposed approach developed by the UDWQ / EPA workgroup for assessing whether GSL is supporting its designated uses. This process provides a structured methodology that can be used to determine whether GSL should be considered impaired and included in category 5 (303(d) section) of the Integrated Report (IR). Also presented is a description of the GSL ecosystem, a summary of the beneficial uses and applicable water quality standards. This appendix details the proposed decision making approach proposed for making a listing determination for GSL.

The decision making approach focuses on the open waters of GSL defined by DWQ as all open waters at or below the 4,208-foot lake elevation. The lake has been further divided into subclasses based on hydrologic boundaries and are as follows; 5A-Gilbert Bay, 5B-Gunnison Bay, 5C-Bear River Bay, 5D-Farmington Bay. A preliminary decision making framework for the GSL transitional wetlands is currently under development by the workgroup but is not discussed here.

The decision making approach outlined in this document represents the first step in the assessment process, which is to determine whether the GSL supports its beneficial uses or if it does not support its beneficial use and should be considered as impaired. This process may be iterative and conclusions may change as additional data become available.

### **2.B.2. GSL Ecology and Conditions**

The GSL is a terminal waterbody with highly variable chemical and biological conditions. Salinities in the GSL range from about 2% salinity in Farmington and Bear River bays to about 30% salinity in Gunnison Bay. Gilbert Bay is intermediate at 12-14% salinity. Gilbert Bay and Farmington Bay often develop density stratification resulting from hypersaline water from Gunnison Bay underflowing the less saline water of Gilbert Bay and in turn the hypersaline water from Gilbert Bay underflowing the less saline water of Farmington Bay. This strong stratification can last months or even years. As a result, dissolved oxygen concentrations range from saturation (circa 4 mg L<sup>-1</sup>) in the shallow brine layer to anoxia and strongly reducing conditions in the deep brine layers. Reduced forms of sulfur and metal ions have been described in the deep brine layer. Due to the extreme and variable conditions, the ecosystems of the various bays are dominated by different types of biota. Gilbert Bay is recognized for its prolific

populations of brine shrimp and brine flies while Bear River and Farmington bays are generally too low in salinity to support significant brine shrimp populations. Rather, Bear River and Farmington bays are dominated by corixids and, to a lesser extent, by brine flies and midges. Algal and bacterial populations are also vastly different among the bays. Fish are absent from the open waters of the GSL except when a combination of low lake levels and high spring runoff contributes to a “freshening” of Farmington and Bear River bays. During these times bluegill, carp and other minnows have been observed and numerous pelicans, herons, egrets and cormorants have been observed actively feeding in these bays.

Abundant brine shrimp populations have been noted in the open water of Gilbert Bay. These brine shrimp have an interesting life cycle which includes a dormant overwintering stage known as cysts or eggs. Depending on temperature and freshwater inflow, these eggs begin hatching in April or early May. Several molting cycles result in various instar stages until mature adults begin appearing in early June. Brine shrimp densities may reach 3-5 individuals per liter that presents heavy grazing pressure on their preferred algal species, *Dunaliella viridis*. This simple food chain dependence results in two–five cycles of population spikes and crashes that are caused by a periods of overgrazing and depletion of *Dunaliella* followed by a crash in brine shrimp numbers, followed by exponential growth of *Dunaliella* which in turn, provides for exponential growth of brine shrimp. This cycling continues until late October or early November. Massive production of countless cysts occurs during the last few growth cycles of brine shrimp-providing the eggs for the next season’s production. Cyst densities are so numerous that 20 to 30 million pounds of cysts are commercially harvested each winter and sold to food shrimp growers throughout the world. This harvest is carefully monitored by the Utah Division of Wildlife Resources in order to ensure sufficient cyst densities remain so that this brine shrimp population is sustained from year to year.

#### **2.B.2.1. Applicable Beneficial Uses and Narrative Water Quality Criteria for GSL**

The State of Utah’s Rule R317-2 for Standards of Quality for Waters of the State lists GSL as a category 5 waterbody that is protected for “*primary and secondary contact recreation, waterfowl, shore birds and other water-oriented wildlife including their necessary aquatic organisms in their food chain, and mineral extraction.*” Except for mineral extraction, these are the GSL’s beneficial uses that must be protected under the Clean Water Act.

The lack of unimpacted reference sites with which to compare GSL and its unique ecosystem make it difficult to establish expected conditions for this water body. At present, numeric water quality criteria have not been established for GSL, rather the State’s narrative criterion applies and states:

*“it shall be unlawful, and a violation of these regulations, for any person to discharge or place any waste or other substance in such a way as will be or may become offensive such as unnatural deposits, floating debris, oil, scum or other nuisances such as color, odor or taste; or cause conditions which produce undesirable aquatic life or which produce objectionable tastes in edible aquatic organisms; or result in concentrations or combinations of substances which produce undesirable physiological responses in desirable resident fish, or other*

*desirable aquatic life, or undesirable human health effects, as determined by bioassay or other tests performed in accordance with standard procedures.”*

### **2.B.3. Background on Beneficial Use Support Impairment Determinations Using Indicators**

Assessing whether GSL supports its beneficial uses requires a methodology for interpreting Utah’s narrative water quality standards. The methodology need not prove a particular contaminant is the cause of impairment to a beneficial use but should outline the procedures to be used to determine if a beneficial use is at risk.

For the assessment plan described in this appendix, we propose to identify both *direct* and *indirect* indicators of GSL ecosystem health. Thereby, quantitative measures of multiple lines of evidence will be used to determine whether the beneficial uses are at risk.

**2.B.3.1. Direct Indicators of Beneficial Use Support:** The most direct evidence for determining whether a waterbody is supporting its beneficial uses is to measure the use itself. Examples of direct indicators include:

- *Contact Recreation Use Support:* Quantifiable measures of amount of contact recreational use in the waterbody and documented illnesses related to recreational use of the waterbody;
- *Waterfowl/ Shorebird Use Support:* Quantifiable measures of the shorebird or waterfowl population and documented deaths occurring in the waterbody attributed to the waterbody; and
- *Aquatic Life Use Support:* Brine shrimp densities; zooplankton abundance and diversity, algal abundance and diversity.

Direct indicators are often difficult to develop due to the amount of data required, the influence of multiple stressors, and the need for “reference” sites for the development of thresholds or benchmarks. Because GSL is such a unique ecosystem, biological indices for macroinvertebrates, zooplankton, and algal species are not readily available in the literature or are not applicable to GSL.

Therefore, the use of direct indicators as the best measure of beneficial use support will require additional study and time to develop

**2.B.3.2. Indirect Indicators of Beneficial Use Support:** When it is difficult to gather or interpret data for direct indicators, *indirect indicators* can serve as surrogates to evaluate whether environmental conditions support an associated beneficial use. Examples of indirect indicators include the following types of measurements:

- *Contact Recreation Use Support:* E. coli or pathogen indicator densities have been correlated with human health impacts in fresh water environments. In marine environments Enterococci is used;

- *Waterfowl/ Shorebird Use Support:* Mercury concentrations in avian dietary items and in the livers, eggs and other tissues of birds have shown a link between mercury bioaccumulation and affects on avian reproduction and health; and
- *Aquatic Life Use Support:* Metals concentrations in the water column are linked with impacts to aquatic life (macroinvertebrates), waterfowl or shorebirds) based on toxicity studies.

#### **2.B.4. Weight of Evidence Decision Making Approach**

Using a weight of evidence approach, one would identify the important direct and indirect indicators needed to assess beneficial use attainment, identify thresholds for those indicators, and use the preponderance of evidence to make a conclusion regarding impairment. Using the weight of evidence approach, it is not necessary to prove that a particular contaminant is impacting a beneficial use but rather to demonstrate, using multiple lines of evidence that the beneficial use is at risk. Additional work would then be necessary to identify the causative factor/constituent.

Possible outcomes of an assessment include:

- a) A determination that the waterbody is not impaired and placement of the waterbody into the appropriate IR category;
- b) A determination that the condition of the waterbody is unknown and further study or action is warranted;
- c) A determination that the waterbody is impaired with placement into IR category 5.

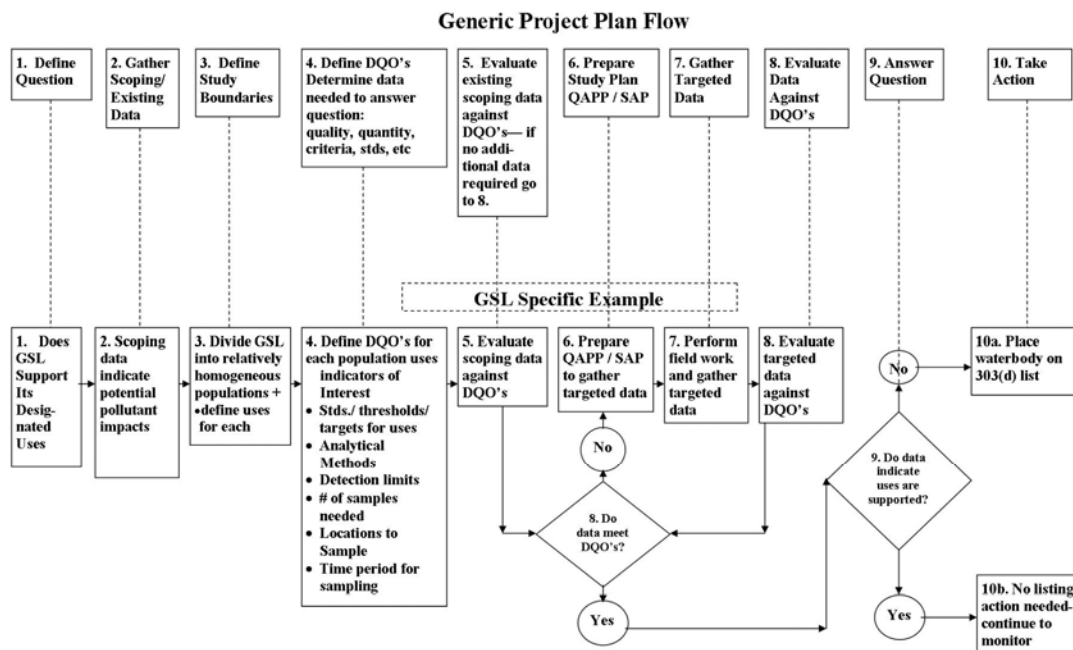

If the waterbody is impaired and 303(d)-listed, further efforts may be needed to establish numeric criteria or targets in the Total Maximum Daily Load (TMDL) process.

##### **2.B.4.1. Logic Diagram for Weight of Evidence Decision Making Approach**

The Decision Making Approach is an iterative process where large complicated issues are broken down into manageable study units. A series of questions, answers, and decisions are made in each unit so that incremental progress is made towards solving the larger issue of whether or not GSL supports its beneficial uses.

Figure 2.B.1 illustrates the systematic process by which data are gathered and evaluated in each unit. The UDWQ/EPA work group followed the steps outlined in this process to develop the draft GSL assessment plan presented in this document for mercury and nutrient impacts as raised by the 2006 Integrated Report public comments.

**Figure 2.B.1. Generalized Flow Diagram**

### Step 1: Define the Question.

The first step in the assessment plan is to clearly identify the study question of interest. This focuses the effort so that efficient progress toward decision making can occur.

### Step 2: Evaluate Existing/Scoping Data

The second step in the assessment plan is to evaluate existing/scoping data to determine if further study is warranted and clearly define the areas requiring evaluation.

### Step 3: Define Study Boundaries

In Step 3, existing/scoping data are used to help define relatively homogeneous study boundaries. Study boundaries may be defined by physical, chemical, contaminant, or biological characteristics within an area. The goal is to narrow the study area so that the fewest number of samples may be collected to generate representative data. This step focuses the study so that defensible conclusions may be drawn.

Currently, the narrative criteria are applied to the GSL as one waterbody. However, since different bays of GSL have different salinities and hydrology, the State has segmented the GSL into relatively homogenous areas for individual evaluation (see page XX for a discussion of proposed segmentation of GSL - need to reference page where this discussion is provided).

#### **Step 4: Define Data Quality Objectives (DQOs)**

In Step 4, the information needed to answer the question in Step 1 is identified. Establishing data quality objectives and assessment methods requires that the following types of information be defined prior to additional data collection or analysis:

- Important indicators of impairment for which data has been or needs to be gathered (examples include nutrient concentrations, dissolved oxygen values, measures of biological diversity, toxic chemical concentrations, etc.);
- An assessment framework in which threshold values or contaminant benchmarks (water quality standards, contaminant limits) are identified for each indicator that may be used to distinguish between fully supporting and impaired conditions (see Tables SS-1 through TL-5 for examples). The assessment framework serves as a precursor to development of an assessment methodology for GSL. The State's Assessment Methodology currently describes the process for making impairment determinations for lakes/reservoirs and streams/rivers. This approach will be reviewed for its applicability to GSL.
- Physical locations and biological communities that need to be sampled and how sampling sites will be selected (random vs. targeted sampling.);
- The amount of data of each type needed to make an assessment;
- Statistics that will be applied in evaluating the data;
- Temporal requirements for sampling (daily impacts, seasonal impacts, annual impacts, etc.);
- Special sampling protocols that need to be followed to ensure a representative sample is available for laboratory analysis;
- Analytical methods and detection limits required to produce data that may be compared with thresholds/benchmarks for decision making;
- Field and laboratory quality control procedures needed to demonstrate adequate precision and accuracy of sample collection and measurements; and
- Defined decision rules that predetermine the actions that will be taken based on the results of the data interpretation. (A decision rule is a statement that describes the actions to be taken based on the data assessment outcome.)

#### **Steps 5 Through 8: Analysis of Existing Data Against DQOs and Additional Targeted Data Gathering to Fill Data Gaps**

In Steps 5 through 8, data are evaluated against the DQOs developed in Step 4 to ensure that the quality and quantity of data meets the study needs. In addition, the assessment frameworks are used to interpret the data. If additional data must be gathered to answer the question from Step 1, a thorough quality assurance project plan (QAPP) is devised and executed.

### **Step 9: Answering the Question Posed in Step 1.**

Using the DQO's and assessment framework, the data is interpreted and the question in Step 1 is answered.

### **Step 10: Taking Action Based on Data Analysis**

Once the question from Step 1 is answered, the decision rules identified in step 4 during the DQO process are implemented and the appropriate predefined action is taken.

The initial assessment of GSL will apply this weight of evidence decision making approach in evaluating the potential impacts of nutrient and mercury risks to waterfowl, shorebirds and aquatic-dependant life. If this approach is found to be useful, other beneficial use assessments for human health and recreational use will follow.

### **2.B.4.2. Mercury and Nutrient Specific Assessment Logic Diagrams and Assessment Frameworks**

Given the concerns raised about possible impacts to GSL from mercury and nutrients, the UDWQ/EPA workgroup concentrated its efforts on developing a decision making approach that could be used to evaluate risks from these pollutants. The work group prepared decision making logic diagrams for both assessments of mercury and nutrient impacts to the aquatic life beneficial use of the GSL. In addition, the work group drafted assessment frameworks to be applied to each GSL segment. These figures and tables are provided at the end of this appendix (see Figures SS-1 and TL-1, Tables SS-1 through TL-5). The following sections provide a brief narrative description of the activities associated with each step in the diagrams, proposed actions, and schedule for an assessment determination. These frameworks are in draft form for public review and comment. It is recognized that these frameworks will continue to be refined and updated with additional information and improved science.

#### **2.B.4.2.1. Mercury Assessment Decision Making Approach**

Figure SS-1 shows the decision making approach for determining if mercury associated with the GSL ecosystem poses a significant health risk to avian species.

**Step One: Define Study Question** – Are avian species (water fowl and shorebirds) at risk from mercury exposure associated with GSL?

For this first step, the question is whether mercury associated with the GSL ecosystem (water, sediment, and aquatic life) poses a health risk to avian species that use GSL. Risk in this case is the potential for significant impacts to waterfowl and shorebird species composition and abundance (mercury impacts to health, survival, and reproduction).

## **Step 2: Gather and Evaluate Existing or Scoping Data to Determine if Further Study is Warranted.**

Existing GSL data indicate elevated concentrations of mercury in the water column, duck muscle, liver and blood, and in eared grebe livers and breast muscle. Mean concentrations of mercury in brine shrimp during 2006 were nearly three times higher than those in 1996 and may be approaching avian dietary effects thresholds. Further evaluation of mercury risk to aquatic-dependant life is warranted.

## **Step 3: Establish Study Boundaries.**

The DWQ has proposed to divide GSL into five sub-areas or subclasses based on specific physical, chemical and geographical characteristics. Each proposed GSL sub-area will be evaluated individually because some sub-areas of GSL may pose a greater risk to avian populations than others. Interactions between sub-areas may also be studied. Sensitive avian species as well as species in which the contribution of mercury from GSL is distinguished from mercury contributions from other locations during the birds' life cycle will be included in future studies. Input from experts will be sought to identify the most appropriate avian species and critical time periods for study if additional data are required. The existing eared grebe and migratory duck data will also be evaluated.

## **Step 4: Define Data Quality Objectives and Assessment Methodologies Against Which Existing and Future Data Will be Evaluated and Interpreted.**

Indicator identification – **Table SS-1** provides the Assessment Framework and examples of direct and indirect indicators chosen for further consideration in this study. It is likely that total mercury and methyl mercury in the diet, livers, muscle and eggs of targeted avian species will be the indicators of choice for this decision-making process. Experts will be consulted to assist in the choice of the most valuable indicators of avian risk. Water column and sediment concentrations may be evaluated if suitable benchmarks can be identified.

### **a. Identification of threshold values (contaminant tissue limits or ambient biological or constituent thresholds) –**

**Table SS-1** provides the Assessment Framework with threshold values and benchmarks for various indicators of interest based on literature values. Expert opinion will be sought to assist in the application of the most appropriate benchmarks for risk assessment.

### **b. Choice of media and locations to be sampled –**

**(1) Dietary source samples** - The primary dietary items of shorebirds and waterfowl will be evaluated. Existing brine shrimp, brine fly, brine fly larvae, midge larvae and corixid

data will be evaluated. Additional data will be gathered on dietary contribution if required and may include sediment data since some species ingest sediment while foraging. The major feeding areas for these food sources will be targeted across GSL.

**(2) Avian tissue samples** - Existing tissue data (liver and muscle data) available for eared grebes and other birds will be evaluated against the DQO's and benchmarks. Archived tissue samples that were collected as part of the Great Salt Lake Selenium Study will be assessed for suitability for mercury analysis to supplement the database. Efforts will be made to ensure that additional tissue sampling planned by UDEQ, UDNR, and USFWS will be coordinated to fill the data gaps identified through this process.

**(3) Water column and sediment samples** - Existing water column and sediment data will be evaluated as well as data that are soon to be available as part of the 2007 Regional Geographic Initiative (RGI) grant to UDEQ from the EPA.

**c. Choice of avian species to be studied** – Eared grebe, and migratory duck data are available and will be evaluated against DQO's and benchmarks. In addition, expert opinion will be sought to determine the best target species to ensure that sensitive species and those species representing GSL exposures are included.

**d. Number of Samples-** Either, 30 to 50 samples from a relatively homogeneous population that produces reasonable estimates of population statistics such as mean values, standard deviations, etc. will be used or a power analysis will be performed to optimize the number of samples required for future sampling efforts.

**e. Statistics to be applied** – Expert opinion will be sought to determine the proper statistic to use to evaluate against the threshold values. It is anticipated that means, ranges, variances, standard deviation, and tests for significance of difference will be employed in data analysis for data that are collected randomly and are normally distributed. If the contaminant data are not normally distributed (ex. non-detects, species migration) the data could be analyzed using non-parametric tests.

**f. Temporal requirements for sampling** – Ideally, dietary samples and tissues samples would be collected upon arrival of a species at the lake and then again just before migratory departure from the lake. In this way, changes in the birds' body burden as a result of GSL use could be determined. For non-migratory species, collection of tissue samples should coincide with maximum use of the lake eco-system or most sensitive life stage. Expert input will be sought to determine the most appropriate sampling schedule.

**g. Field protocol requirements** – Clean techniques should be employed for collection of mercury samples. Laboratory requirements for holding time and temperature must be followed.

**h. Laboratory analytical methods** – Comparable laboratory methods used in previous studies will be employed. Detection limits for total mercury and methyl mercury must be below the thresholds/benchmarks for decision making.

**i. Field and laboratory quality control procedures** – All required laboratory quality control requirements must be adhered to as specified in the Laboratory's Quality Management Plan or as described in Standard Operating Procedures. This should include at a minimum requirements for initial demonstration of capabilities for analysts, use of standard curves, internal standards, matrix spikes, duplicates, and blanks. Field quality control procedures should include preparation of field blanks and field duplicates (when appropriate) at a frequency of 10%.

**j. Decision rules** – Data evaluation and potential outcomes and conclusions are presented in Figure SS-2. The predetermined actions that will be taken based on the results of the data interpretation are identified.

### **Steps 5 Through 9: Collection of Additional Data, Evaluation against DQO's, and Data Interpretation**

The next step is to compare the available scoping data against the draft DQOs and thresholds captured in the Assessment Framework (see Tables SS-1). Available data for the recommended indicators will be summarized and compared to the thresholds identified in the Assessment Frameworks. The workgroup plans to review these data in 2008 to determine if the original questions concerning risks to the beneficial use can be answered.

If sufficient data exist, the questions identified in Step 1 (related to impairment determinations) will be made using the weight-of-evidence approach. If there are data gaps or the results are inconclusive, the workgroup will develop a monitoring plan designed to collect the necessary information to make a decision. If additional studies are necessary to better understand certain dynamics of the GSL ecosystem, the decision making process will be repeated, starting with Step 1 and based on a link to the original question of interest. For example, of paramount interest is the rate of methylation and proportion of mercury exposure from GSL sources vs sources elsewhere in the flyway and nesting grounds.

### **Step 10: Decision Rule and Planned Actions**

A decision rule is a statement that describes the actions to be taken based on the data assessment outcome. **Figure SS-2** provides the possible conclusions that could arise from data analysis and provides the decision rule to be followed. The decision rule for this decision making process is as follows: if it is concluded through this weight-of-evidence approach that waterfowl or shorebirds or other waterbirds are at risk due to mercury exposure associated with the open waters of GSL, the segments of the

waterbody for which this risk applies will be placed into category 5 - list of impaired waters. Otherwise, the segments will be placed into the appropriate IR category and routine monitoring will continue.

#### **2.B.4.2.2 Nutrient Decision Making Approach**

Figure TL-1 shows the generalized decision making approach for evaluating whether nutrient enrichment is impacting aquatic-dependant life in GSL.

##### **Step 1: Define Study Question: *Are aquatic-dependant life in GSL at risk due to elevated nutrient concentrations?***

For nutrients and GSL, the question of interest is whether aquatic-dependant life in GSL are at risk due to elevated nutrient concentrations. Aquatic life use support refers to environmental conditions which support the following biological assemblages: macroinvertebrates, zooplankton and algal communities that comprise the GSL foodweb. Macroinvertebrates are animals lacking a backbone but large enough to be seen without the use of a microscope. Examples of the types of macroinvertebrates found in GSL ecosystems include corixids (water boatmen), and brine flies. Zooplankton are small animals that drift in open water including amphipods, copepods, cladocera and isopods. Copepods, cladocera and brine shrimp are the dominant zooplankton. Given the economic importance brine shrimp play in GSL, brine shrimp are considered separately from zooplankton in the evaluation of whether GSL supports aquatic-dependant life.

##### **Step 2: Scoping or Existing Information:**

A cursory review of existing data for the GSL raised concerns about the possible impacts of nutrient enrichment on the GSL ecosystem.

##### **Step 3: Define Study Boundaries:**

The evaluation of risk from nutrient enrichment focuses on the entire open water GSL ecosystem with consideration for different salinity concentrations found in specific areas of GSL. Since the aquatic life found in different areas are influenced by salinity concentrations, the indicators and subsequent data quality objectives reflect differences in the ecosystem which occur below and above 6% salinity. For example, dominance of blue-green algae as an indicator is assigned to all of GSL, however, data indicate limited likelihood of experiencing blue-green algal blooms which exceed the proposed thresholds in the highly saline areas of Gilbert and Gunnison Bay. In addition, the aquatic life community found in certain areas of GSL varies with increases or decreases in salinity. Zooplankton are commonly found when the salinity is less than 6% compared to a brine shrimp-dominated community in areas containing greater than 6% salinity. (See Tables TL-1 through TL-5)

##### **Step 4: Define Data Quality Objectives (DQOs) and Assessment Methodologies Against Which Existing and Future Data Will be Evaluated and Interpreted:**

As stated previously, the risk of nutrient enrichment to GSL focuses on potential impacts to aquatic life. Nutrients affect aquatic life in a variety of direct and indirect pathways.

Increased nutrient concentrations can result in increased phytoplankton growth as measured with chlorophyll a concentrations. These changes may result in increasing numbers of algal blooms covering areas of GSL (evaluated with chlorophyll a concentrations, Trophic State Index values, or aerial imagery). As algae die, bacteria consuming the decaying algae reduce the dissolved oxygen available in the water column, resulting in oxygen depletion. These various linkages support the evaluation of multiple direct and indirect indicators when considering nutrient enrichment.

The Assessment Frameworks (Tables TL-1 through TL-5) detail the direct and indirect indicators that may be used to evaluate possible impacts to the aquatic life beneficial use. Direct indicators of zooplankton composition or macroinvertebrate composition are mentioned as possible direct measures of aquatic life use support. However, developing the tools and thresholds to interpret the health of those communities may require ongoing studies.

In the interim, several indirect indicators have been identified as useful tools to evaluate possible nutrient impacts on the aquatic life in the GSL.

The list of primary indirect indicators includes:

- Algal biomass (measured by chlorophyll a concentrations)
- Trophic State Index Values
- Dominance of Blue-green algae
- Number, extent and duration of algal blooms as evaluated by aerial imagery
- Increasing nutrient concentrations
- Deviation from expected Redfield ratios
- Dissolved oxygen concentrations (less than 2 mg/L)

The different indicators each allow the evaluation of aspects of potential risk to the aquatic life from nutrient impacts. By describing the different questions that can be answered with each indicator, or a suite of indicators analyzed in combination, decisions can be reached about risk to the resource. Used in concert, these indicators will be evaluated as multiple lines of evidence following a weight-of-evidence approach to answer the question of risk to aquatic life use. Figure X describes the general decision making process that will be followed to reach impairment decisions. Clear indication of risk of nutrient enrichment is evidenced if GSL concentrations were well above the thresholds for multiple indicators.

In some cases, the answer to the question is not straight-forward and may generate additional questions that need to be answered. Additional questions that extend beyond the scope of the original question are captured as Phase II (future) studies. These studies may help clarify associations between different parameters and the impacts to aquatic life.

## **Steps 5 Through 9: Collection of Additional Data, Evaluation against DQO's, and Data Interpretation**

The next step is to compare the available scoping data against the draft DQOs and thresholds captured in the assessment frameworks (see Tables TL-1 through TL-5). Available data for the recommended indicators will be summarized and compared to the thresholds identified in the assessment frameworks. The workgroup plans to review these data in spring 2008 to determine if the original questions concerning risks to the beneficial use can be answered.

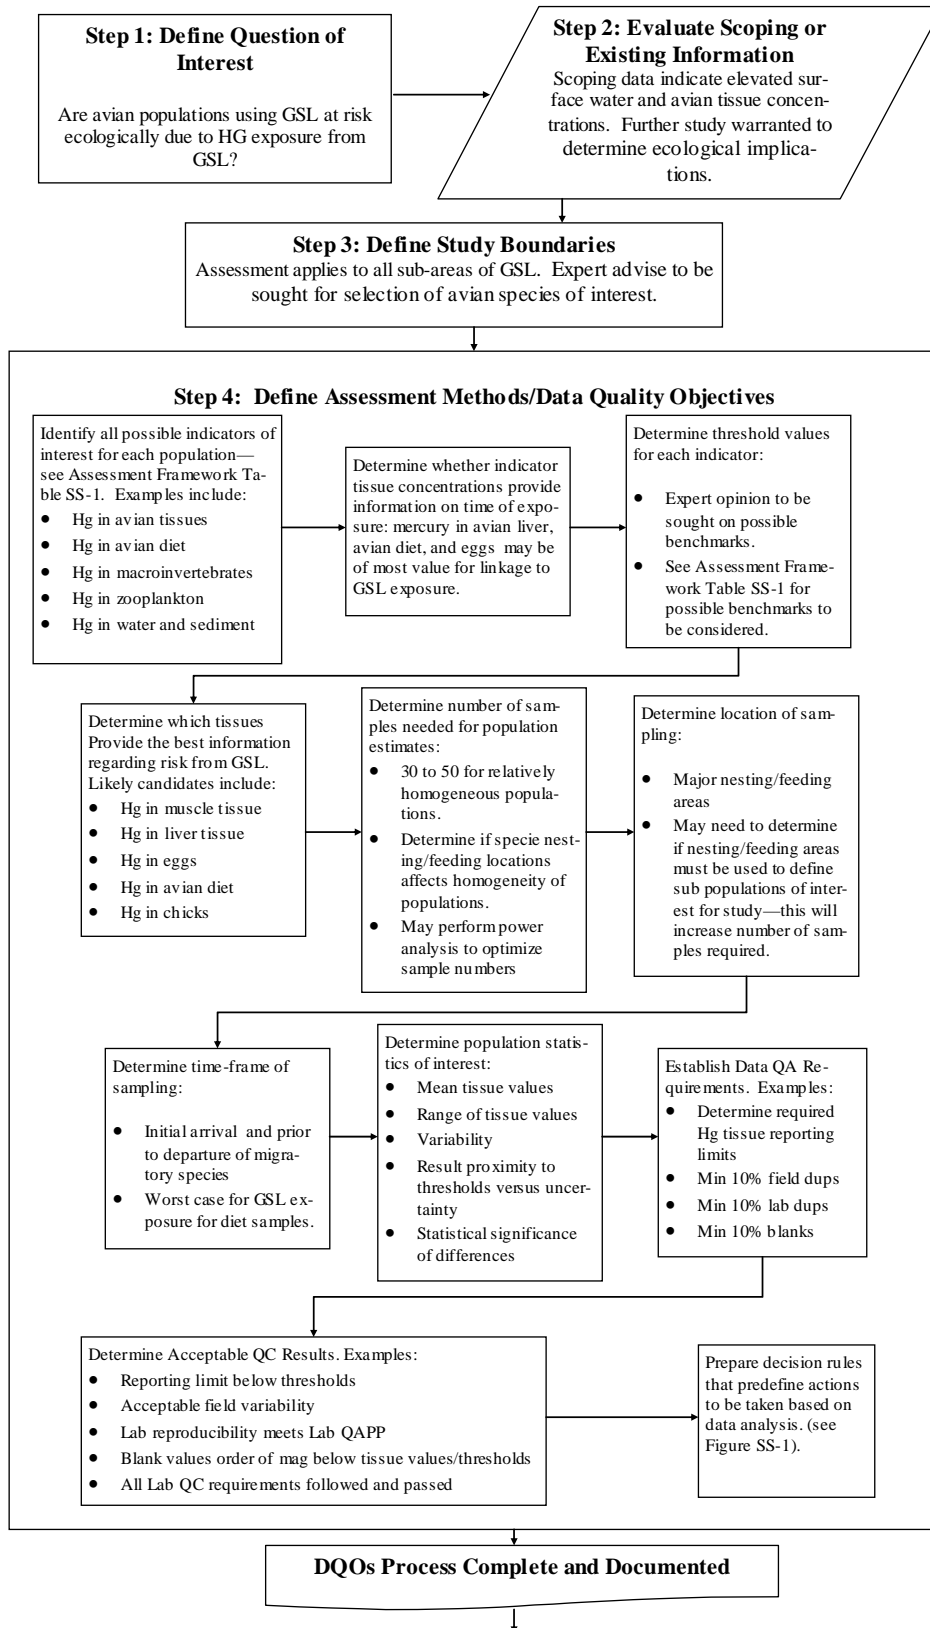

If sufficient data exist the questions identified in Step 1 (related to impairment determinations) will be made using a weight-of-evidence approach. If there are data gaps or the results are inconclusive, the workgroup will develop a monitoring plan designed to collect the necessary information to make a decision. If additional studies are necessary to better understand certain dynamics of the GSL ecosystem, the decision making process will be repeated, starting with Step 1 and based on a link to the original question of interest.

### **Step 10: Decision Rule and Planned Actions**

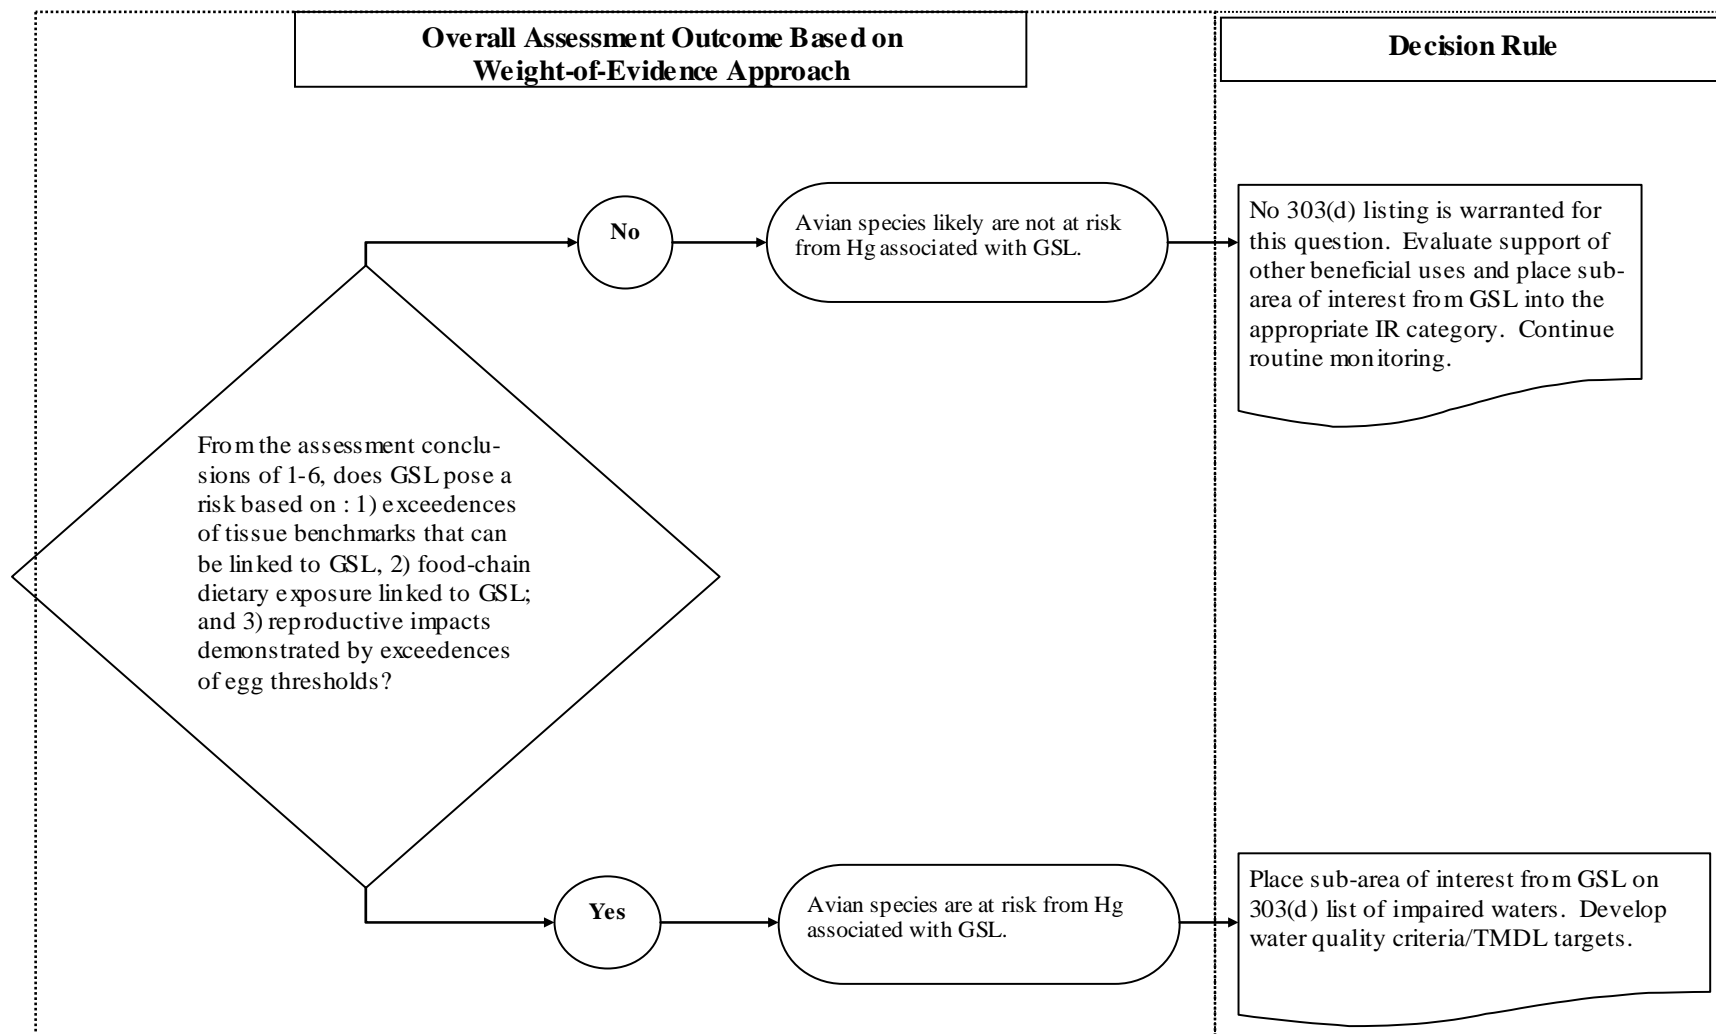

A decision rule is a statement that describes the actions to be taken based on the data assessment outcome. Figure SS-2 provides the possible conclusions that could arise from data analysis and provides the decision rule to be followed. The decision rule for this decision-making process is as follows: if it is concluded through this weight-of-evidence approach that waterfowl or shorebirds or other waterbirds are at risk due to nutrient enrichment associated with the GSL, the segments of the waterbody for which this risk applies will be placed into category 5, the list of impaired waters. Otherwise, the segments will be placed into the appropriate IR category and routine monitoring will continue.

**Table TL-1. Gilbert Bay Draft Assessment Framework  
GSL All areas with waterfowl/ shorebird use**

| Biological (biological assemblages), Chemical and Physical Integrity | Direct Indicators                 | Indirect Indicators               | Utility (applicability) of the Indicator (1-3 with 3 as highest) | Confidence in the Indicator | Threshold Value Available (Y/N) + Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Exposure Location/Timeframe Represented by Indicator |
|----------------------------------------------------------------------|-----------------------------------|-----------------------------------|------------------------------------------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Waterfowl and Shorebirds                                             | Waterfowl and/or shorebird health | total Hg in diet                  | 3                                                                | 3                           | total-Hg: Acute poisoning effects at 20 mg/kg (USEPA 1997). 10 mg/Kg (RAIS); 0.5 ppm (64 ug/kg bw/day) LOAEL for mallard ducks (Rfd = 21 ug/kg bw/d) (Heinz 1975); 0.3 ppm in fish caused reproductive effects in loons (Barr 1986). Effects levels of forage fish on avian species lies in the range of 0.077 to 0.3 ppm (Mercury Study Report to Congress). 0.3 to 0.4 ppm in prey resulted in reduced egg laying in loon (Schuehammer 1991 MRTC). Common dietary effect level 0.50 ug/g dw (USGS 2006). Free-living common loons show negative impacts when mercury in prey fish reaches 0.2 to 0.4 mg/kg wet weights (Barr 1986, Nocera and Taylor 1998, Scheuhammer 1995). | GSL linked exposure                                  |
|                                                                      |                                   | total Hg in kidney                | 3                                                                | 2                           | total-Hg: Acute poisoning effects at 20 mg/kg (USEPA 1997). 20 mg/Kg (RAIS). 30 ug/g fresh weight in liver and kidney showed neurological effects (Scheuhammer 1991).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Not determined                                       |
|                                                                      |                                   | total Hg in liver                 | 3                                                                | 3                           | total-Hg: Acute poisoning effects at 20 mg/kg (USEPA 1997). 20 mg/Kg (RAIS); 23 ppm in liver of black ducks showed reproductive effects (Findley and Stendell, 1978 Mercury Report to Congress). total-Hg> 20 ug/g fresh weight of soft tissues extremely hazardous to avian species (Findley et al. 1979). 30 ug/g fresh weight in liver and kidney showed neurological effects (Scheuhammer 1991). Liver concentrations in adult pheasants and mallard ducks of 2 to 12 ug/g fresh weight linked to decreased hatchability of eggs (Scheuhammer 1991). Diagnosis of Hg poisoning with 20 ppm Hg in liver and presence of microscopic lesions.                                 | Fairly recent exposure                               |
|                                                                      |                                   | total Hg in blood                 | 3                                                                | 3                           | High risk associated with values >3.0 ug/g ww (USGS 2006).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Fairly recent exposure                               |

|                                                                      | Waterfowl and/or shorebird reproductive success (hatching, fledgling) | total Hg in eggs (first egg or unhatched eggs are best) | 3                                                                | 3                           | total-Hg: 0.5 mg/Kg (RAIS); 2 to 3 ppm total-Hg in loon eggs correlated with reduced eggs laying and nest and territorial fidelity in loon (Schuehammer, 1991 MRTC). Values of 0.5 to 2.0 ug/g total-Hg in eggs sufficient to reduce viability, hatchability, embryo survival and chick survival in nonmarine birds (Thompson 1996). Embryo deformities occur in eggs with 1 ug/L total-Hg with sensitive embryos experiencing mortality with Hg as low as 0.74 ug/g (Heinz and Hoffman 2003). Often used reproductive effect endpoint for total-Hg in eggs is 0.80 ug/g (Heinz 1979, Henny et al. 2002). Adverse effects on reproduction occur at egg concentrations of 0.05 to 2.0 mg/kg total-Hg wet weight. (Global Mercury Assessment). Bird effects in general occur at egg concentrations of 0.05 to 5.5 mg/kg wet weight for total-Hg with majority around 0.5 to 1.0 mg/kg (Global Mercury Assessment). LOEC for avian egg = 0.5 ppm fresh weight (AEHHIM) | Represents recent exposure or mobilization from other tissues - local conditions and/or migratory conditions. Walsh 1990 suggested that eggs provide good indicator of mercury exposure in vicinity of nesting site in for immediate pre-laying season. (AEHHIM) |
|                                                                      |                                                                       | total Hg in diet                                        | 3                                                                | 3                           | total-Hg: 10 mg/Kg (RAIS); 0.5 ppm (64 ug/kg bw/day) LOAEL for mallard ducks (Rfd = 21 ug/kg bw/d) (Heinz 1975); 0.3 ppm in fish caused reproductive effects in loons (Barr 1986). Effects levels in forage fish lies in the range of 0.077 to 0.3 ppm (Mercury Study Report to Congress). 0.3 to 0.4 ppm in prey resulted in reduced egg laying in loon (Schuehammer, 1991 MRTC).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | GSL linked exposure                                                                                                                                                                                                                                              |
